Errata

On Coppock (2017), *Statistics, Politics and Policy* 8(1)

This note lists ten errors in "Did Shy Trump Supporters Bias the 2016 Polls? Evidence from a Nationally-representative List Experiment," published in *Statistics, Politics and Policy* 8(1), doi 10.1515/spp-2016-0005. **None of them changes a conclusion of the paper.** Each is recorded because a reader who took the page at its word would be taking away something the paper's own data do not support. Entries 1 to 4 are misstated numbers: the first two substantive, the next two arising from rounding before subtracting and noted for completeness. Entries 5 and 6 are not numbers at all and are the two that reach a figure and a table rather than a sentence: a set of row labels that carry each other's values, and a misspelling in the note under Table A1.

Every corrected value below is computed from the deposited data at the time this document is rendered. The code and output supporting each correction are at github.com/active-maintenance-aec/coppock_2017a.

1. Standard error of the difference between the two estimates

> The bootstrapped standard error of this difference is **3.4** points, indicating that is not statistically significantly different from zero.

Corrected:

> The bootstrapped standard error of this difference is **3.3** points, indicating that is not statistically significantly different from zero.

2. Difference between the direct question and the list experiment

> Recall that the direct question estimate of Trump support was 32.5%, for a **2.9** percentage points difference.

Corrected:

> Recall that the direct question estimate of Trump support was 32.5%, for a **3.0** percentage points difference.

The published figure is the difference of the two rounded shares. The rounded difference is 3.0, which is what Table A1 reports for the same quantity, so the article disagrees with its own appendix.

3. Share reporting other, would not vote, or undecided

> Respondents split 32.5% for Donald Trump and 37.0% for Hillary Clinton, while **30.5%** reported that they would vote for other candidates, would not vote, or were still undecided.

Corrected:

> Respondents split 32.5% for Donald Trump and 37.0% for Hillary Clinton, while **30.4%** reported that they would vote for other candidates, would not vote, or were still undecided.

The published figure is 100 minus the two rounded shares. The three remaining response categories carry 30.4 per cent of the weight.

4. Length of the income scale in Equation 1

> A brief justification of this specification: all variables except for 7-point Party ID and **22-point** Income are indicators, so not many modeling choices must be made.

Corrected:

> A brief justification of this specification: all variables except for 7-point Party ID and **24-point** Income are indicators, so not many modeling choices must be made.

The deposited income variable takes 24 distinct values, 1 through 24, with every value present, and the deposited script enters it as it stands.

5. The income quintile rows of Figure 1 and Table A1 carry each other's labels

> **Below 20th income percentile**, **20th-40th income percentile**, **40th-60th income percentile**, **60th-80th income percentile**, **Above 80th income percentile**

Corrected:

> **20th-40th income percentile**, **40th-60th income percentile**, **60th-80th income percentile**, **Above 80th income percentile**, **Below 20th income percentile**

The deposited script builds the grouping factor with its levels typed in alphabetical order and its labels typed in substantive order, so each income row is printed under the label belonging to the group before it and the lowest quintile is printed as the highest. Every other block in the same call lines up, because only the income levels sort differently under the two orders. The direction is not a matter of interpretation: income_quintile is a self-describing character variable whose five categories partition the deposited household income measure, and the row the article prints as the bottom quintile reports N = 1,038, which is the size of the second quintile; the bottom quintile has 804.

The changed artifact is the five labels alone. No estimate, standard error or sample size moves, and no conclusion turns on it: the article's claim about income is that the groups did not diverge widely, which holds under either labelling. The maintained rewrite prints the labels the data supports, which is why its income rows disagree with the published ones in the ground truth.

6. A misspelling in the note to Table A1

> Adjusted **direction** question estimates are predictions from a logistic regression.

Corrected:

> Adjusted **direct** question estimates are predictions from a logistic regression.

The column the note describes is headed Direct question, and every other mention of the estimator in the article and in the deposited script spells it that way. The misspelling is in the authors' own source as well as on the published page. It was found while setting Table A1 for the remastered edition, which reads a float cell by cell where the token gate drops its interior on both sides.

7. A dropped word in the abstract

> A list experiment conducted on the same respondents yields an **estimate** 29.6%

Corrected:

> A list experiment conducted on the same respondents yields an **estimate of** 29.6%

The word is missing on the published page and in the deposited manuscript. The sentence has one reading with it and none without, so what is supplied is recoverable from the document rather than chosen for it. Found by reading the abstract against the published page while preparing the remastered edition.

8. A dropped word in the Combined Estimate section

> we should discount the value **the** combined estimate

Corrected:

> we should discount the value **of the** combined estimate

The same omission as entry 7 and the same reasoning: the sentence is about the value of the combined estimate, there is no second reading, and the word is absent from the published page rather than from this reading of it.

9. A narrative citation set without its parentheses

> Aronow et al. **2015** also propose a joint test

Corrected:

> Aronow et al. **(2015)** also propose a joint test

Every other narrative citation in the article parenthesises its year: Blair and Imai (2012), Glynn (2013), Imai (2011), Dropp (2015). The authors' own source sets this one with the same macro as the others, so the parentheses were lost in typesetting.

10. A second dropped word in the abstract

> the list experiment estimate is actually lower than **direct** question estimate

Corrected:

> the list experiment estimate is actually lower than **the direct** question estimate

The same omission as entries 7 and 8, in the same sentence as entry 7, and missing from the deposited manuscript as well. Everywhere else the article writes "the direct question estimate"; the sentence's own subject, "the list experiment estimate," takes the article too. Found while setting entry 7 for the remastered edition.
