Errata

On Schwarz and Coppock (2022), *The Journal of Politics* 84(2)

This note lists 11 corrections to "What Have We Learned about Gender from Candidate Choice Experiments? A Meta-Analysis of Sixty-Seven Factorial Survey Experiments," published in *The Journal of Politics* 84(2), doi 10.1086/716290. It also carries four entries of a second kind, which quote a passage and propose no change to it: the Results sentence that says the trimmed estimate drops the bottom and top 5% where the code drops 3.0 and 6.0 per cent, the design sentence that counts 49 papers where the deposit has 50 bibliography keys, the appendix sentence that counts nine digitally measured experiments in seven papers where the deposit marks ten in eight, and two cells of Figure 3 that print an earlier revision of one study's estimates. **No correction and no note here changes a conclusion of the paper.** Entries 1 to 5 and 7 to 11 are errors in the published record, recorded because a reader who quoted it would be misled. Entry 6 is not an error but a restoration: the journal keyed three figure captions to panel letters its own compositor added, and the authors' figures label those panels by name. Entries 12 to 15 are neither: they are carried as the paper published them, and are described under their own heading below.

Every corrected value in entries 1 to 6 is computed from the deposited replication archive (10.7910/DVN/R27ULT) at the time this document is rendered. Entries 9 to 11 correct the reference list, which the deposit cannot speak to: entry 9 is verified against the cited manuscript's own title page and the authoritative record at Crossref, and the two URLs against the authors' own bibliography file in the archived working folder, one of them against the article's own reference list as well. Entry 7 is a single letter and quotes the sentence it stands in, and entry 8 is a misspelled word in an appendix figure. Entry 6 quotes the published captions themselves, which is the only thing that can settle what a caption says. The maintained code is at github.com/active-maintenance-aec/schwarz_coppock_2022.

1. The share of studies with a positive effect is overstated, in two places

Published, p. 659:

> Across the 67 studies we summarize, **three-fourths** find a positive effect of being described as a woman.

Corrected:

> Across the 67 studies we summarize, **70%** find a positive effect of being described as a woman.

Published, p. 664:

> We observe considerable study-to-study variation, although **more than three-fourths** of the studies show a positive effect.

Corrected:

> We observe considerable study-to-study variation, although **70%** of the studies show a positive effect.

Of the 67 study-level estimates, 47 are positive, 19 are negative and 1 is exactly zero. The positive share is 70.1 per cent, which is below three-fourths rather than above it. The claim the two sentences make is unaffected: positive effects are the large majority.

2. The counts of negative and of significant estimates

Published, p. 661:

> We see a very consistent pattern in favor of women candidates on average: 47 estimates are positive (**23** significant) and **18** are negative (**11** significant).

Corrected:

> We see a very consistent pattern in favor of women candidates on average: 47 estimates are positive (**29** significant) and **19** are negative (**6** significant).

The deposited estimates divide into 47 positive, 19 negative and 1 exactly zero, which is the only division summing to 67. The published 47 plus 18 sums to 65.

The corrected counts of significant estimates are those of the confidence interval rule the deposited script itself applies, which gives 29 and 6. The published 23 and 11 correspond to no significance rule the deposited estimates support, and not merely to a rule with a different threshold: both counts rise as a threshold is relaxed, so no threshold can produce 23 and 11 at once. Tightening the threshold until only 23 positive estimates remain significant leaves 5 negative ones; loosening it until 11 negative estimates are significant leaves 43 positive ones. A test of p below 0.05 gives 19 and 2, and cannot be what was done in any case, because 19 of the 67 studies carry no p-value. What procedure produced the published pair is therefore unknown; the correction states what the deposited rule gives.

The direction of the correction favours the article's own claim: more positive estimates reach significance than were reported, and fewer negative ones.

A count of significant estimates is the warrant for the sentences that follow it, so those were re-asked under the corrected rule. The article asserts a significance verdict for three studies one at a time, all on published p. 661, and all three keep the verdict it gives them:

Ono and Yamada is negative and significant, Kage, Rosenbluth, and Tanaka is positive and significant, and Horiuchi, Smith, and Yamamoto is exactly zero. The same paragraph names five further contexts as showing negative effects and claims significance for none of them, and the deposit gives a negative estimate in every one. No sentence in the article changes.

3. Figure 3 covers 37 experiments, not 36

Published, p. 663:

> Figure 3 shows the CATEs of candidate gender, conditional on respondent gender, for the **36** experiments where we were able to identify respondent gender.

Corrected:

> Figure 3 shows the CATEs of candidate gender, conditional on respondent gender, for the **37** experiments where we were able to identify respondent gender.

The deposited respondent-gender file carries 37 studies, and the published figure itself draws 37 rows in each of its two panels. Figure 3 is correct as printed and is not reproduced here; only the sentence describing it miscounts. Nothing plotted is affected and neither pooled estimate moves.

4. Appendix Figure A.18 prints none of its estimates

Figure A.18, Costa (2020), USA - Lucid, is the one study in the appendix whose randomized attribute levels are whole tweets. At the width the appendix uses, those row labels push the plotting panel, the points, the confidence intervals, the estimate labels and the horizontal axis off the right edge of the page. What is printed is a column of truncated sentences, an axis title cut off after four letters, and no data. None of the 10 conditional effects the figure is drawn from appears on the page.

The appendix promises this figure in terms: it closes its introduction by saying that in the remainder "we show the study-by-study estimates that make up Figure A.1". For Costa (2020) it shows none of the 10, which is the one place in the appendix where that sentence does not hold. Figure A.1 itself is unaffected, since it is drawn from the estimates rather than from these figures.

Nothing is wrong with the estimates themselves; they are in the deposited archive and are unchanged. The figure as it should have appeared:

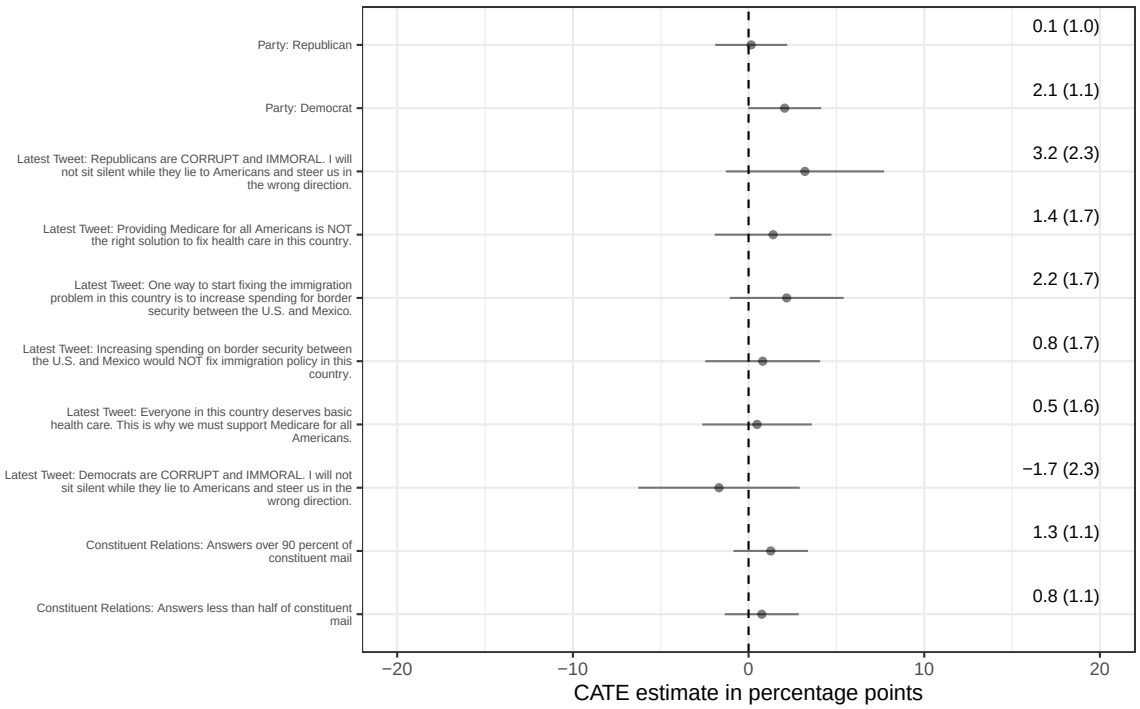

Figure A.18 (redrawn)

Note: Figure A.18 redrawn from the deposited replication archive by `maintained/figure_a2_a45_cate_by_study.R`, with the row labels wrapped and the canvas widened so the panel fits the page. Every estimate, standard error and interval is unchanged; only the layout differs. The 43 other per-study appendix figures print their estimates correctly, and all 1888 of those labels reproduce.

5. Appendix Table A.1 omits one of the studies it summarizes

Published, app. p. A.1:

> Table A.1 lists **43** studies.

Corrected:

> Table A.1 should list **44** studies.

The appendix carries 44 per-study CATE figures, A.2 through A.45, one for each study in the meta-analysis. Simas and Murdoch (2019) is plotted at Figure A.44 and has no row in Table A.1, so the table describes 43 of the 44. The study is present in the deposited data and in every pooled estimate; only the summary table omits it.

The omission is not confined to the table. The appendix introduces Figure A.1 as the distribution of the CATEs "conditional on each of the attributes listed in Table A.1", so the table is where a reader learns what that figure covers, and the unlisted study contributes 2 of the figure's 954 conditional effects. Two estimates in 954 cannot move the distribution, so

the appendix's takeaway from Figure A.1 stands as written. What the missing row costs is the account of one study's attributes, which is the whole of what Table A.1 exists to give.

6. Three figure captions key panel letters the authors' own figures do not print

Published, p. 663:

> Figure 2. Conditional average effect of candidate gender, conditional on **candidate race: A, black candidate; B, white candidate**

Corrected:

> Figure 2. Conditional average effect of candidate gender, conditional on **candidate race**

Published, p. 664:

> Figure 3. Conditional average treatment effects of candidate gender by **respondent gender: A, female respondents; B, male respondents**

Corrected:

> Figure 3. Conditional average treatment effects of candidate gender by **respondent gender**

Published, p. 664:

> Figure 4. Conditional average treatment effects of candidate gender by **respondent partisanship: A, Democratic respondents; B, Independent respondents; C, Republican respondents.**

Corrected:

> Figure 4. Conditional average treatment effects of candidate gender by **respondent partisanship**

The panel letters are the journal's and not the authors'. The deposited code draws all three of these figures with the panels labelled in words, and the published figures print A, B and C instead and add a key to the caption to say what the letters mean. The correction drops the key and lets the panels name themselves, which is what the deposited figures do. Nothing plotted differs: no estimate, standard error, interval or study is affected, and the letters are the whole of what changes.

7. A plural noun where the sentence wants a modifier

Published, p. 663:

> Finally, we consider the effects of gender, conditional on respondent characteristics, in particular by gender and **partisans** affiliations.

Corrected:

> Finally, we consider the effects of gender, conditional on respondent characteristics, in particular by gender and **partisan** affiliations.

The error is the authors' own and survived a copy-edit that touched the same sentence: the submitted manuscript in the archived working folder carries the same words but opens them "Lastly" where the page prints "Finally". The same paper writes "candidate partisan affiliation" correctly on published p. 657. One letter changes and nothing else does: no estimate, count, figure or study is affected, and the sentence means what a reader already takes it to mean.

8. An appendix figure misspells an attribute in two row labels

Published, app. p. 13:

> **Expereience**: Three years experience; **Expereience**: No Experience

Corrected:

> **Experience**: Three years experience; **Experience**: No Experience

Both labels are rows of Figure A.12, Carnes and Lupu (2016), Argentina. The deposited estimates file spells the word correctly, while a 2018 presentation figure in the archived working folder carries the same misspelling, so regenerating the figure from the deposit corrects it. The word is the whole of what changes: no estimate, standard error, or study is affected.

9. The Clayton and Nyhan (2020) manuscript has six authors

Published, p. 666:

> **Clayton, Katherine, and Brendan Nyhan**. 2020. "Who Will Defend Democracy? Evaluating Tradeoffs in Candidate Support among Partisan Donors and Voters." Unpublished manuscript.

Corrected:

> Carey, John, Katherine Clayton, Gretchen Helmke, Brendan Nyhan, Mitchell Sanders, and Susan Stokes. 2020. "Who Will Defend Democracy? Evaluating Tradeoffs in Candidate Support among Partisan Donors and Voters." Unpublished manuscript.

The manuscript at the URL the entry itself prints carries six authors on its title page, in the alphabetical order given above. Crossref, doi 10.33774/apsa-2019-wjva3-v4: Nyhan, Helmke, Sanders, Clayton, Carey, Stokes, and the same six on every posted version of the preprint. The short form is therefore Carey et al. (2020), which the article uses as a study label in six further places: two rows of Table 1, two rows of the appendix's study table, and the titles of appendix Figures A.16 and A.17. The appendix's own reference list carries the same two-author entry. Only the labels change: no estimate, standard error, sample size or study is affected, and neither of the two experiments the label names is misidentified.

10. An appendix reference prints a URL cut off at the edge of the page

Published, app. p. 37:

> https://preprints.apsanet.org/engage/api-gateway/apsa/assets/orp/resource/item/**5d02becd39ef04**will-defend-democracy-evaluating-tradeoffs-in-candidate-support-among-partisan-donors-and-voters.pdf

Corrected:

> https://preprints.apsanet.org/engage/api-gateway/apsa/assets/orp/resource/item/**5d02becd39ef0400184a49fd/original/who-**will-defend-democracy-evaluating-tradeoffs-in-candidate-support-among-partisan-donors-and-voters.pdf

The line the appendix sets this URL on runs 206pt past the right edge of the paper, so 23 characters of it are drawn where no reader can see them and the printed URL leads nowhere. Two independent records give the same missing span: the authors' own gender.bib in the archived working folder, and the ARTICLE'S OWN reference list on published p. 666, which prints the whole URL because its two-column measure broke the line somewhere else. Nothing but the URL changes: the entry names the same manuscript, which is the one entry 9 corrects the authorship of.

11. An appendix reference prints a URL with a character missing

Published, app. p. 39:

> https://web.stanford.edu/** **tomz/working/Tomz-VH-Repositioning-Conjoint-2016-04.pdf

Corrected:

https://web.stanford.edu/~tomz/working/Tomz-VH-Repositioning-Conjoint-2016-04.pdf

The tilde is drawn as a blank: the published page shows a gap at 300 dpi and the text layer returns a space, so the character is absent from the document rather than lost in reading it. Without it the URL is not a personal-directory URL and does not resolve. The authors' own gender.bib in the archived working folder carries the tilde. The article's reference list cites a different address for the same manuscript and so cannot settle this one.

Carried, and not corrected

The four entries below are different in kind from the 11 corrections in this note. Each quotes a passage this edition reprints exactly as the paper published it, and proposes no change to it.

Three of them are places where the page and the deposited archive disagree and the deposit cannot say which is right: a trimming rule that the code applies differently from the text and the table label, a count of papers, and a count of digitally measured experiments. The fourth is two cells of a figure drawn from an earlier revision of one study's estimates than the deposit holds. In each case a corrected token could only be set by deciding what the authors meant, which is theirs to say, and none of the four reaches an estimate the paper rests a conclusion on. Each is recorded here because an edition that silently reproduced them would leave a reader unable to tell a faithful reprint from an uncorrected error.

12. The trimmed estimate is described as dropping five per cent from each tail, and the code does not

Published, p. 662:

> Importantly, even when we trim **the bottom and top 5%** of point estimates from our analysis, our meta-analytic estimate remains robust, suggesting that our findings are not merely attributable to a handful of outlying studies.

Table 2 (published p. 663) labels the row this sentence describes "Trimmed (middle 90% of estimates)", so the label and the sentence agree that five per cent is cut from each tail. The deposited code keeps the estimates above the 2nd percentile and below the 95th. That drops 2 of the 67 studies at the bottom (3.0 per cent) and 4 at the top (6.0 per cent), retaining 61, or 91 per cent rather than 90. The published row is the result of that rule: 0.0176 (SE 0.0030, interval 0.0118 to 0.0234) over 61 studies. The symmetric rule the sentence describes retains 59 and gives 0.0198 (SE 0.0029, interval 0.0141 to 0.0255); both are in `maintained/output/table_2_trim_sensitivity.csv`.

Neither the sentence nor the row label is corrected. Rewriting them to match the code, or rerunning the code to match them, would each fix a sample definition, and the deposit cannot say which sample the authors meant. No conclusion changes: the trimmed estimate

is positive with an interval that excludes zero under either rule, and moves by 0.0022, so the sentence's claim that a handful of outlying studies does not drive the result holds under both.

13. The design section counts 49 papers and the deposit assigns 50 bibliography keys

Published, p. 659:

> In total, we located 67 experiments from **49 papers**.

The deposited study-level file assigns 50 distinct bibliography keys to the 67 studies. The two counts differ by 1, and the deposit is self-consistent in showing 50, so it cannot say whether the article treats two keys as one source or miscounts. No corrected count is set, because setting 50 would assert that every key is a distinct paper, which is what the deposit cannot show. The count describes the literature search and enters no estimate: no conclusion of the paper changes, and no study or effect depends on how many papers the 67 experiments came from.

14. Appendix B counts nine digitally measured experiments in seven papers and the deposit marks 10 in 8

Published, app. p. 34:

> Figure 1 in the main text includes estimates from **nine experiments in seven papers** that we were only able to obtain by digitally measuring the coefficient plots included in the published papers.

The deposited study-level file marks 10 experiments from 8 papers as having had their estimates measured from a picture, in a free-text note field. The appendix says nine experiments in seven papers. Whether the appendix's nine leaves out one of the marked 10, or the note field marks one the authors did not count, cannot be settled from free text, so no corrected pair is set. The validation exercise that follows the sentence is a test of the measurement method on one study and does not depend on the count: no conclusion of the paper changes, and the 10 marked estimates are in the pooled results either way.

15. Two cells of Figure 3 print an earlier revision of one study's estimates

Published, p. 663, Figure 3:

> Female respondents: Sen (2017), USA, SSI 2: **6.0** (2.2)
>
> Male respondents: Sen (2017), USA, SSI 2: **0.5** (2.0)

The figure prints 6.0 and 0.5 for Sen (2017), USA, SSI 2, in the female and male respondent panels. The deposited respondent-gender file gives 5.9 (2.2) and 0.4 (2.0); the standard errors agree with the page. The deposited study-level file carries the revised Sen SSI 2 estimate that Figure 1 reproduces exactly, so the conditional-effects file is one revision behind the figure the article printed. No value is set here, because replacing the two cells would present the deposit's earlier file as the figure's intended source, which the deposit cannot show. Every other estimate and standard error in the figure reproduces, as do both pooled estimates and the difference between them, so no conclusion of the paper changes: two study-level points of 74 differ by a tenth of a percentage point.
