Errata

On Blair, Coppock and Moor (2020), *American Political Science Review* 114(4)

The maintained replication code behind these errata is at https://github.com/active-maintenance-aec/blair_coppock_moor_2020 and is archived at Zenodo at https://doi.org/10.5281/zenodo.24168286, a DOI that always resolves to the latest version.

This note lists fifteen corrections to "When to Worry about Sensitivity Bias: A Social Reference Theory and Evidence from 30 Years of List Experiments," published in the *American Political Science Review* 114(4), doi 10.1017/S0003055420000374: ten misstated numbers, one sentence that describes the estimates incorrectly as a result, two misprinted figure labels, and two page ranges in the reference list printed as a first page alone. **None of them changes a conclusion of the paper.** Ten are in the article's text, two are in its figures, two are in its reference list, and one, entry 7, is in its online appendix. Entries 1, 2, 3, 4, 5, 6, 7, 8, 9, and 11 restate a quantity the article also prints in Table 4, and in each case Table 4 is right and the sentence is not. The sentences that carry the paper's findings, and Table 4 itself, are unaffected.

Every number in a corrected sentence below is computed from the deposited replication archive (10.7910/DVN/YUXHZT) at the time this document is rendered, including the numbers that were not wrong. The code and output supporting each correction are at github.com/active-maintenance-aec/blair_coppock_moor_2020.

Bold marks the corrections, and only what is bold has changed. Everything else in a corrected sentence reads exactly as the page prints it, figures included. A figure an entry does not correct is recomputed from the deposit like every other, then stated at the article's own precision, usually whole points; each one reproduces the published figure, and this document refuses to render if one does not. A corrected figure is stated to one decimal place, so a correction smaller than a point can be seen at all. Where the fuller value of an uncorrected figure matters it is given in the note beneath the entry.

The first six entries are substantive: the number a reader would quote is wrong by more than a point, and the first two turn on a sign. Entries 6 to 10 differ from the article's own figure, in Table 4 or for entry 10 in Figure 2a, by less than a point, which is exactly why they need a decimal to be visible at all. Entries 12 and 13 are panel labels: a misspelling in Figure 3, and a panel of Figure 4 that names the wrong prediction. The last two were found by an audit that sends every printed reference entry whole to Crossref and checks the authoritative record back into it.

1. The sexual orientation underreporting estimate carries the wrong sign

> For questions thought to be subject to overreporting, the average estimate of sensitivity bias is –2 percentage points; for underreporting, the estimate is **+2** percentage points.

Corrected:

> For questions thought to be subject to overreporting, the average estimate of sensitivity bias is –2 percentage points; for underreporting, the estimate is **−1.0** percentage points.

Table 4 prints –0.01 for the same quantity. The paper's conclusion for this literature, that sensitivity bias in questions about attitudes towards gays and lesbians cannot be distinguished from zero, is unaffected.

2. The racial prejudice 95 per cent predictive interval

> The 50% predictive interval reaches from +1 to +7 points, but the 95% predictive interval admits large negative biases (**−16** points) to large positive biases up to **16** points.

Corrected:

> The 50% predictive interval reaches from +1 to +7 points, but the 95% predictive interval admits large negative biases (**−5.2** points) to large positive biases up to **12.8** points.

Table 4 prints [–0.05, 0.12] for this interval. The lower bound in the text is roughly three times the one the table carries.

3. The width of the turnout 95 per cent predictive interval

> This uncertainty is also reflected in the very wide predictive intervals: the 50% interval is 13 points wide and the 95% interval is **45** points wide.

Corrected:

> This uncertainty is also reflected in the very wide predictive intervals: the 50% interval is 13 points wide and the 95% interval is **37.4** points wide.

Table 4's own interval for turnout is [–0.12, 0.26], which is 38 points wide, so the sentence disagrees with the table as well as with the data.

4. The vote buying predictive intervals

> In the bottom row of Figure 4a, we show the 50% predictive interval from –14 to **−2** points and the 95% predictive interval from **−27** to **+10** points.

Corrected:

> In the bottom row of Figure 4a, we show the 50% predictive interval from –14 to **−2.7** points and the 95% predictive interval from **−24.9** to **+8.1** points.

Table 4 prints [–0.14, –0.03] and [–0.25, 0.08] for the same two intervals.

5. The width of the religious prejudice credible interval

> This estimate is in the expected direction, but the credible interval is **13** points wide and includes zero.

Corrected:

> This estimate is in the expected direction, but the credible interval is **11.4** points wide and includes zero.

Table 4's own interval for religious prejudice is [–0.07, 0.04], which is 11 points wide.

6. The upper bound of the vote buying credible interval

> In the top row is the estimated average sensitivity bias across studies for vote-buying questions (black diamond), –8 points with a 95% credible interval stretching from –13 to **−3** points.

Corrected:

> In the top row is the estimated average sensitivity bias across studies for vote-buying questions (black diamond), –8 points with a 95% credible interval stretching from –13 to **−3.7** points.

Table 4 prints –0.04 for the same bound.

7. The average bias across all underreporting studies

> Second, as shown in Table 4, the average sensitivity bias in the case of underreporting is **−3** points (SE: 1 point).

Corrected:

> Second, as shown in Table 4, the average sensitivity bias in the case of underreporting is **−3.5** points (SE: 1 point).

Table 4 prints –0.04, which rounds to –4 rather than –3 at whole-point precision.

8. The lower bound of the racial prejudice credible interval

> For questions about racial prejudice, our summary guess is that if anything, subjects overreport racist attitudes by approximately 4 points (95% CI **−3** to +9).

Corrected:

> For questions about racial prejudice, our summary guess is that if anything, subjects overreport racist attitudes by approximately 4 points (95% CI **−2.4** to +9).

Table 4 prints –0.02 for the same bound, which is –2 rather than –3 at whole-point precision. The estimate the sentence hedges as "approximately 4 points" is 3.8 and is correct at the precision it states, so it is left as published.

9. The lower bound of the authoritarian overreporting predictive interval

> Based on 21 studies, our meta-analysis estimate of the average level for studies in which overreporting is predicted is +14 points and the 50% predictive interval suggests a likely level of sensitivity bias between **+4** to +24 points.

Corrected:

> Based on 21 studies, our meta-analysis estimate of the average level for studies in which overreporting is predicted is +14 points and the 50% predictive interval suggests a likely level of sensitivity bias between **+4.5** to +24 points.

Table 4 prints 0.05 for the same bound.

10. The sample size at which a list experiment becomes preferable on RMSE grounds

> For a study with 1,000 subjects, the bias must be greater than **5.5** points to prefer a list experiment; at 2,000, the bias must be greater than 4 points.

Corrected:

> For a study with 1,000 subjects, the bias must be greater than **5.6** points to prefer a list experiment; at 2,000, the bias must be greater than 4 points.

The RMSE indifference curve the article's own Figure 2a plots crosses at 5.57 points at this sample size, so a bias of 5.5 points would not in fact prefer the list experiment. The companion bound at 2,000 subjects crosses at 3.94 and holds as stated.

11. Only one of the two sexual orientation estimates has an unexpected sign

> **These estimates both have** an unexpected sign relative to the **predictions and are not** distinguishable from zero.

Corrected:

> **Only the overreporting estimate has** an unexpected sign relative to the **predictions, and neither is** distinguishable from zero.

The sentence follows directly from the misstated figure corrected above. Underreporting predicts a negative difference between the direct question and the list experiment, and the underreporting average is –1.0 points, which is the sign predicted. Overreporting predicts a positive difference, and the overreporting average is –1.8 points, which is not. Both credible intervals contain zero, so the second half of the sentence stands as published.

12. A misspelling in the label of Figure 3(a)

> **Difference-in-prevalance**

Corrected:

> **Difference-in-prevalence**

The figure's own caption and Note spell the word correctly; the panel label is the only place it does not.

13. Figure 4(c) labels the racial prejudice studies with the wrong prediction

Racial prejudice (**overreporting**)

Corrected:

Racial prejudice (**underreporting**)

Table 4 lists the racial prejudice studies under Underreporting and has no overreporting row for them, and every other panel of the figure is labelled with the prediction its row of Table 4 carries.

14. The Tourangeau and Yan reference prints a first page in place of a page range

Psychological Bulletin 133 (5): **859**.

Corrected:

Psychological Bulletin 133 (5): **859–83**.

Crossref, doi 10.1037/0033-2909.133.5.859, gives the article's pages as 859 to 883. The corrected range keeps the reference list's own style, which drops the leading digits a last page shares with the first.

15. The Yu, Tian and Tang reference prints a first page in place of a page range

Metrika 67: **251**.

Corrected:

Metrika 67: **251–63**.

Crossref, doi 10.1007/s00184-007-0131-x, gives the article's pages as 251 to 263. The corrected range keeps the reference list's own style.
